Dear Hiring Team,

I am applying for the **Senior Go Engineer – OSS Package Upgrade** role. Over the past three years I have built, shipped, and maintained production systems in Go on Linux, and the part of that work I enjoy most is exactly what this role is about: keeping a codebase healthy while its dependencies move underneath it.

WHAT I BRING

- **Go and dependency management.** I work in **Go modules** day to day — **go.mod** and **go.sum**, **semantic versioning**, transitive resolution and version conflicts, and pinning a dependency back when an upgrade is not yet safe. I have upgraded third-party libraries across live services, resolved the resulting conflicts, and updated every downstream call site touched by a breaking API change.
- **Build and test debugging.** I take ownership of failures rather than routing around them: compile errors, linker errors, failing or flaky tests, race conditions, goroutine and memory leaks. I have used **go build**, **go test**, the race detector and **pprof** profiling to isolate root causes, and I still write the regression test so the same bug cannot return quietly.
- **Git, review, and clean patches.** Branching, rebasing, merge-conflict resolution including in `go.mod`, and splitting large migrations into reviewable commits. Every change I submit carries the validation evidence a reviewer needs — build output, test results, and a note on what was touched and why.
- **Linux, scripting, and CI/CD.** Bash for engineering automation, and **GitHub Actions** pipelines with build and test stages that **gate every merge**. Presubmits that fail fast and precisely are the cheapest defect detection available, and I have built them to be both strict and fast.

ON THE TOOLING I HAVE NOT USED YET

The posting names **Bazel** and, as a nice-to-have, **Copybara**. I have not worked with either in production, and I would rather say so plainly than overstate it. What I can promise is the underlying discipline is already mine: hermetic builds, explicit dependency graphs, reproducible targets, and CI that validates a change before it lands. **Bazel** is a build-system frontend over exactly the same `go build` and `go test` graph, and I would expect to be productive on it quickly — I have already been reading up on WORKSPACE, BUILD files, and `rules_go` in preparation for this conversation.

WHY THIS ROLE

The scope appeals to me: owning upgrades end to end, from risk analysis of the dependency tree through to a migration report with validation results and outstanding issues. It is unglamorous, high-leverage engineering, and it plays to the part of my work I care about most — keeping other engineers unblocked by keeping the platform sound. I am based in India and open to relocating to Pune, Chennai, Hyderabad, or Bangalore, and I would be glad to confirm my availability for the interview at your convenience.

I have attached my resume and would welcome the chance to walk through a specific dependency upgrade I have handled, including how I scoped the blast radius, what broke, and how I proved the fix.

Warm regards,
Ishwar Kalmegh
